2012 Annual Report—35th Edition

## STOCK AND FLOW

## AUSTRALIA

The annual stock and flow of HD patients during the period 2007-2011 is shown in Figures 5.1, 5.2 and 5.3.

There were 8,929 patients receiving HD treatment at 31<sup>st</sup> December 2011, an increase of 4%; of these 22% were hospital based, 50% were in satellite centres and 9% at home. Home haemodialysis is presented in detail from page 5.36.

A total of 1,811 patients received HD for the first time during the year, a slight increase from previous years.

The proportion of all HD patients in each age group is shown in Figure 5.7. There were 2,400 people  $\geq 75$  years receiving haemodialysis, including 422 people  $\geq 85$  years, a rise of 7% from 2010, following a 21% rise for the previous year.

There were 517 transplant operations to people receiving HD treatment, 6% of all HD patients dialysing and 12% of those patients  $< 65$  years.

There were 1,220 deaths in 2011.

## NEW ZEALAND

The annual stock and flow of HD patients during the period 2007-2011 is shown in Figures 5.1, 5.4 and 5.5.

There were 1,591 patients receiving treatment at 31<sup>st</sup> December 2011, a continuation of the trend from 2008-2010.

Hospital based HD (44%), satellite HD (29%) and home HD (27%) have all remained the same for the past three years.

New Zealand is continued on page 4-5.

\* New patients receiving first haemodialysis treatment

Figure 5.6

Figure 5.7

**NEW ZEALAND (continued from page 5-2)**

There were 403 patients who received HD for the first time in 2011, similar to previous years. Seventy eight percent were having their initial dialysis treatment, 20% were previously dialysing with peritoneal dialysis and 2% were failed transplants.

The modal age group for new HD patients was 55-64 years (26%), 9% were <35 years and 35% ≥ 65 years (Figures 5.5 and 5.8). The age distribution of the prevalent HD population was similar (Figure 5.10).

There were 62 HD patients who received transplants in 2011 (47 in 2010). Four patients ≥ 65 years were transplanted.

There were 229 deaths in 2011.

Figure 5.8

Figure 5.9

AUSTRALIA

Blood flow rates in Australia showed a similar picture in 2011 and continued to slowly rise. The proportion receiving a prescribed blood flow rate of 300 mls/minute or higher was 83% in 2011.

Only 3.4% (298 patients) were prescribed < 250 mls/minute.

Blood flow rates are lower in patients dialysing using central venous catheters than in those using AVFs or AVGs (Figure 5.11).

NEW ZEALAND

In December 2011, 72% of patients were prescribed 300 mls/minute or higher.

There were 7% using < 250 mls/minute, many of these were receiving long hour HD.

Figure 5.15

Haemodialysis Frequency (per Week)  
December 2009 - 2011

FREQUENT AND LONG HAEMODIALYSIS

(Figures 5.14 - 5.23)

The proportions of those dialysing > 3 times per week in Australia has plateaued, with no change from 2009. In New Zealand the proportion dialysing more than three times per week continues to increase. The proportions dialysing ≥ 4.5 hours per session has slowly increased. As a result, the proportions dialysing more than the "standard" 12 hours per week continue to rise.

In 2011, 57% and 70% of HD patients were dialysing ≥ 13.5 hours per week in Australia and New Zealand respectively. Figures 5.16-5.20 show these from several perspectives.

Figure 5.16

Figure 5.17

Haemodialysis Duration (Hours per Week)  
December 2009 - 2011

Figure 5.18

Figure 5.19

Figure 5.20

Dialysis frequency and session length vary among the Australian jurisdictions. Patients in Queensland and Victoria are more likely to dialyse more frequently, while patients in New South Wales/ACT and the Northern Territory tend to dialyse longer per session on average (Figures 5.21 - 5.23).

## OUTCOMES AMONG HAEMODIALYSIS PATIENTS

In Australia, there has been little change in haemodialysis patient survival over time, after adjusting for age, diabetes status, sex, race and comorbidities.

In New Zealand, recent cohorts have slightly better survival. Unadjusted survivals are shown in Figures 5.24-5.26.

In both countries, diabetes status and age have marked effects on haemodialysis patient survival. (Figures 5.24 - 5.34).

**Note: For all tables and graphs the times indicated are from the 90th day and not the first treatment.**

Figure 5.25

Figure 5.26

Figures 5.27- 5.28

These figures show survival curves for patients treated with haemodialysis at day 90, adjusted to a median age of 63.1 years for Australia and 57.2 years for New Zealand; non-diabetic primary renal disease; caucasoid race; female gender and no comorbid conditions (lung disease, coronary artery disease, peripheral vascular disease or cerebrovascular disease).

Note: x axis scale refers to time after day 90. PRD = Primary renal disease.

Figure 5.33-5.35 show survival stratified by age at the start of treatment.

## MEMBRANE TYPE AND SURFACE AREAS

### AUSTRALIA Figures 5.35 - 5.38.

Usage of low flux polysulfone dialysers was 1% in 2011, (2% in December 2010, 5% in 2009 and 2008). While the use of high flux polysulphone continues to decrease (1% in 2011, 2010 and 2009, 1.5% in 2008, 7% in both 2007 and 2006, 9% in 2005 and 39% in 2004.

High flux Polysulphone-Helixone increased to 63% in December 2011 from 57% in 2010, 53% in 2009, 49% in 2008 and 39% in 2007. High flux Polyamix increased to 33% this year from 32% last year and 29% in 2009.

There were 99% of patients receiving dialysis with high flux dialysers in 2011 (96% in 2010, 88% in 2009, 81% in 2008 and 72% in 2007).

### NEW ZEALAND Figures 5.36 and 5.39.

Low flux polysulphone decreased to 11% in December 2011, from 13% and 19% in December 2010 and 2009 respectively.

There were 77% (1217 patients) reported as receiving dialysis with high flux dialysers in December 2011, an increase from 72% (1104 patients) in 2010 and 62%(911 patients) in 2009.

## ANAEMIA

In Australia, mean haemoglobin and erythropoietic agent use has gradually reduced. Haemodialysis patients had a higher erythropoietic agent usage despite a similar mean haemoglobin compared to peritoneal dialysis patients (Figures 5.39 - 5.40).

In New Zealand, mean haemoglobin has stabilised at 114 g/L. The increase in erythropoietic agent usage seen over 2004-2011 has reached a plateau.

Figure 5.39

### Mean Haemoglobin Among Dialysis Patients By Survey Period

Figure 5.40

### Use of Erythropoietic Agents By Survey Period

## HAEMOGLOBIN

In Australia, among patients dialysing at 31 December 2011, haemoglobin is <110 g/L in 41% and  $\geq 140$ g/L in 3% of haemodialysis patients, which is the same as the previous two years.

In New Zealand, the corresponding percentages are 44% and 4% respectively. Figure 5.42 shows the proportion of patients with proven or likely cardiovascular disease reported as a comorbidity to the Registry, achieving the clinical target of haemoglobin  $\leq 120$  g/L.

Figure 5.41

Figure 5.42

## HAEMOGLOBIN BY TREATING CENTRE

Figures 5.43- 5.46

The first 2 figures show the median haemoglobin (with inter-quartile range) for individual centres, arranged from lowest to highest. Also shown are the proportion of patients in each centre with a haemoglobin of 110-129 g/L.

In Australia, median haemoglobin for each centre ranged from 105 to 125 g/L for haemodialysis patients and in New Zealand 107-118 g/L.

The proportion of patients in Australia with a haemoglobin of 110-129 g/L in each centre ranged from 30% to 76% for haemodialysis patients and for New Zealand 28% to 55%. For Figures 5.45 and 5.46 the error bars show the 95% confidence intervals.

Figure 5.43

Figure 5.44

Figure 5.45

Figure 5.46

## FERRITIN AND TRANSFERRIN SATURATION

Figures 5.47 - 5.48

In Australia and New Zealand the proportions of haemodialysis patients with ferritin <200 mcg/L and those with ferritin ≥ 500 mcg/L have been relatively stable.

In both Australia distributions of transferrin saturation have been unchanged for the past three years, while in New Zealand the proportion with a transferrin saturation <20 has increased.

Figure 5.47

Figure 5.48

## FERRITIN BY TREATING CENTRE

Figures 5.49 - 5.52

These figures show the proportions of patients in each centre with ferritin of 200-500 mcg/L and transferrin saturation of >20% respectively, as recommended by the CARL guidelines.

In Australia, the proportions of patients with ferritin within this range in each centre varied widely between 2-72% for haemodialysis patients. Similarly large variations between centres were seen for transferrin saturation, between 26-95%. Again, this large variation probably reflects differences in practices, protocols and patient case-mix among centres.

In New Zealand, the corresponding figures for ferritin were between 21-50% for haemodialysis patients and the corresponding figures for transferrin saturation were between 32-72%. In both countries, significant proportions of patients did not have ferritin and transferrin saturation within the recommended ranges, even in the "best performing" centres.

Figure 5.49

Figure 5.50

Figure 5.51

Figure 5.52

### SERUM CALCIUM

Figure 5.53

In Australia the proportions of patients with serum calcium  $\geq 2.4$  mmol/L has stabilised, while, in New Zealand it has increased marginally. Those with  $< 2.2$  mmol/L have increased slightly in Australia, but remained fairly stable in New Zealand.

Figure 5.53

### SERUM CALCIUM BY TREATING CENTRE

Figures 5.54 and 5.55 show the proportions of patients at each centre with serum calcium 2.1-2.4 mmol/L, as recommended by the CARI guidelines. Note: however, that the values in the guidelines are for corrected total calcium, while those in this report are for uncorrected total calcium.

In Australia, the proportions ranged widely between 25-94% for haemodialysis patients, while in New Zealand the corresponding proportions were 32-70%.

Figure 5.54

Figure 5.55

## SERUM PHOSPHATE

Figure 5.56

In Australia, the control of serum phosphate has stabilised after a period of steady improvements. In New Zealand, the proportion with serum phosphate > 1.8 mmol/L has largely remained stable.

Figure 5.56

## SERUM PHOSPHATE BY TREATING CENTRE

Figures 5.57 - 5.58 show the proportions of patients at each centre with serum phosphate 0.8-1.6 mmol/L, as recommended by the CARI guidelines.

In Australia, the proportions ranged widely between 30-72% for haemodialysis patients and in New Zealand, the corresponding proportions were 29-65%.

Figure 5.57

Figure 5.58

### CALCIUM-PHOSPHATE PRODUCT

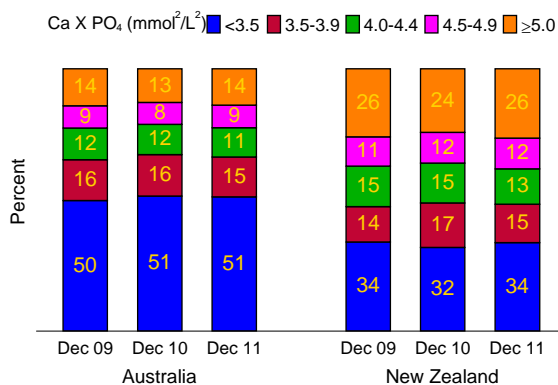

Figure 5.59

In both Australia and New Zealand, improvements in the calcium-phosphate product seen over the last few years have plateaued.

Overall, the proportion of people with high calcium-phosphate product was substantially higher in New Zealand than Australia.

Figure 5.59

#### Calcium Phosphate Product - Haemodialysis December 2009-2011

### CALCIUM-PHOSPHATE PRODUCT BY TREATING CENTRE

Figures 5.60 - 5.61 show the proportions of patients at each centre with calcium-phosphate product <4.0 mmol<sup>2</sup>/L<sup>2</sup>, as recommended by the CARI guidelines.

In Australia, the proportions ranged widely between 45-80% for haemodialysis patients while in New Zealand, the corresponding proportions were 35-65%.

Figure 5.60

Figure 5.61

#### % Haemodialysis Patients with Ca X PO<sub>4</sub> < 4.0 mmol<sup>2</sup>/L<sup>2</sup> New Zealand 31 December 2011

## UREA REDUCTION RATIO

Figures 5.62 and 5.64

Distributions of URR values have shown an increase in those in higher URR groups the past three years. About 8% and 25% of patients on haemodialysis three times a week have URR <65% in Australia and New Zealand respectively.

URR is highest in patients dialysing with an AV graft and lowest in those using catheters Figure 5.63. Of those with URR < 65%, 14% in Australia and 36% in New Zealand had CVC access.

Figure 5.62

<b>Total</b>	<b>303 (24.8%)</b>	<b>921 (75.2%)</b>	<b>1224</b>

## UREA REDUCTION RATIO BY TREATING CENTRE

Figures 5.65 and 5.66 show the median URR in each hospital and Figures 5.67 and 5.68 show the proportions of haemodialysis patients dialysing three times per week in each hospital with URR > 70%, the target recommended by the CARI guidelines.

Median URR values in the respective countries did not vary greatly: 70-82% in Australia and 67-85% in New Zealand. However, the proportions with URR >70% in each unit varied widely, from 55-97% in Australia and 35-95% in New Zealand.

Figure 5.65

Figure 5.66

Figure 5.67

Figure 5.68

## VASCULAR ACCESS AT FIRST TREATMENT

Figures 5.69 to 5.78

The proportion of patients starting haemodialysis with an AVF has continued to rise in both Australia and New Zealand although the majority of patients still commence with a catheter.

In Australia, tunnelled catheters were more common than non-tunnelled, but the reverse was true in New Zealand.

Female, young (age <25years) patients and those patients who were first seen by nephrologists < 3 months before starting haemodialysis (“late referrals”) were less likely to start with an AVF or AVG.

In both Australian and New Zealand indigenous peoples had similar or decreased rates of AVF or AVG at the commencement of dialysis.

ANZDATA does not collect information about indication for HD catheter usage, hence the reason less than half of non-late referred patients commence with a central venous catheter is not known.

Figures 5.80 and 5.81 show the proportion of patients of each hospital starting haemodialysis with AVF/AVG, arranged from the lowest to the highest. In Australia, this ranged widely from 0-80%. The corresponding range in New Zealand was 9-45%. This wide variation reflects differences in practices, protocols, resources and patient case-mix among centres.

Figure 5.80

Figure 5.81

## PREVALENT HAEMODIALYSIS ACCESS

Figures 5.82 - 5.88

In both Australia and New Zealand, the proportions of patients dialysing with an AV graft at 31 December 2011 are declining, while those dialysing with an AV fistulas are stable. The proportions dialysing with catheters have also stabilised.

Female patients in both countries, young (age < 25 years) in Australia or old (age ≥75 years) patients in New Zealand were less likely to be dialysing with an AVF or AVG.

Figure 5.82

Figure 5.84

Figure 5.85

Figure 5.86

Figure 5.87

Figure 5.88

### Prevalent Haemodialysis Access By BMI - 2011

### PREVALENT HAEMODIALYSIS ACCESS

Figures 5.89- 5.90. These show dialysis access among prevalent (rather than incident) patients (those receiving haemodialysis at 31 December 2011).

In Australia indigenous people were more likely to dialyse with an AVF. In New Zealand, Maori and Pacific people were more likely to dialyse with an AVF.

Patients on home haemodialysis have the highest rate of AVF use in both Australia and New Zealand.

Figure 5.89

Figure 5.90

## PREVALENT HAEMODIALYSIS ACCESS

Figures 5.91 - 5.93 show the proportion of haemodialysis patients at each state or hospital dialysing with an AVF/AVG on 31st December, 2011, arranged from the lowest to the highest.

In Australia, the hospital proportions varied widely from 72-100%. The corresponding range in New Zealand was 59-90%. The error bars displayed show the 95% confidence intervals.

Figure 5.92

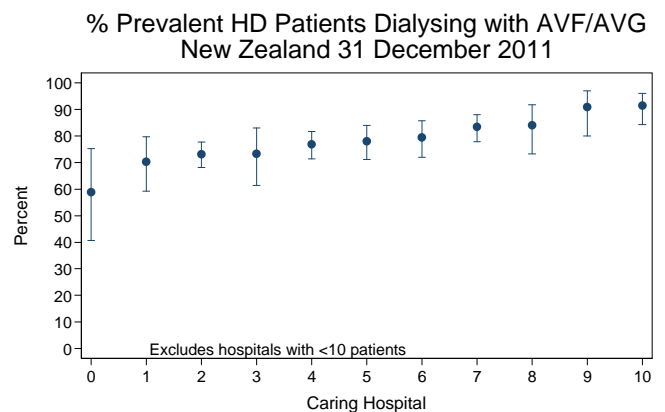

Figure 5.93

## OBESITY AMONG INCIDENT HAEMODIALYSIS PATIENTS

Figures 5.94 - 5.99 show the proportions of incident haemodialysis patients with obesity and morbid obesity. In both Australia and New Zealand obesity rates have been increasing over the last ten years. The proportion of morbidly obese patients starting haemodialysis has doubled from 2002 to 2011 in Australia and increased 20% in New Zealand.

As might be expected, patients with diabetes are more likely to be obese or morbidly obese compared to those without diabetes (Figures 5.99 - 5.100).

Obesity for these analysis is defined as a BMI >30kg/m<sup>2</sup>. Morbid obesity is defined as ≥35kg/m<sup>2</sup>

Figure 5.94

Figure 5.95

Figure 5.96

Figure 5.97

Figure 5.98

Figure 5.99

## OBESITY AMONG PREVALENT HAEMODIALYSIS PATIENTS

Figures 5.100 - 5.105 show the proportion of prevalent haemodialysis patients with obesity and morbid obesity. In both Australia and New Zealand prevalent obesity rates have been increasing over the last ten years. The proportion of morbidly obese patients treated with haemodialysis has nearly doubled from 2002 to 2011 in both countries.

Patients with diabetes are more like to be obese or morbidly obese compared to those without diabetes (Figures 5.104 and 5.105).

Figure 5.100

Figure 5.101

Figure 5.102

Figure 5.103

Figure 5.104

Figure 5.105

## Home Haemodialysis

The proportion of all prevalent dialysis patients who were using home HD in each State was 13% for New South Wales / ACT, 9% Queensland, 7% Victoria, 6% the Northern Territory, 5% Tasmania, 5% Western Australia and 3% for South Australia.

The distribution of numbers of patients receiving home haemodialysis by state is shown in Figure 5.106. As can be appreciated, numbers are greatest in New South Wales and in New Zealand, with substantial numbers also in Victoria and Queensland.

These proportions were lower among older people (Figure 5.108).

Considerable further discussion is contained in chapter 4 .

Figure 5.106

The distribution of prevalent home dialysis patients by age group is shown in Figure 5.107.

Figure 5.107

Queensland	5.40%	5.50%	5.40%	5.10%	4.90%
New South Wales/ACT	9.00%	8.30%	8.10%	7.70%	7.40%
Victoria	4.90%	4.70%	4.40%	4.00%	3.80%
Tasmania	2.10%	2.50%	2.80%	3.30%	2.60%
South Australia	0.50%	0.60%	0.70%	0.90%	1.10%
Northern Territory	3.70%	4.30%	5.60%	5.30%	5.00%
Western Australia	1.50%	1.50%	1.90%	2.50%	2.60%
<b>New Zealand</b>	9.60%	9.50%	10.30%	11.10%	11.20%

The trend in numbers treated with home HD is for different age groups are illustrated for Australia and New Zealand in the Figure 5.109 and 5.110. The Y axes for individual graphs vary – the absolute numbers in the age groups 25 to 64 years are substantially greater than among older patients. However, there has been strong growth in the older age groups in the last few years .

Figure 5.109

Figure 5.110

### Technique failure

The following 3 figures explore the concept of technique failure as applied to home haemodialysis. Each treatment episode can end in a variety of ways. Changes to another dialysis modality (either institutional haemodialysis or peritoneal dialysis) are considered a "failure", as is death. Follow-up is censored at transplantation, or 31 Dec 2011.

Figure 5.111

Figure 5.112

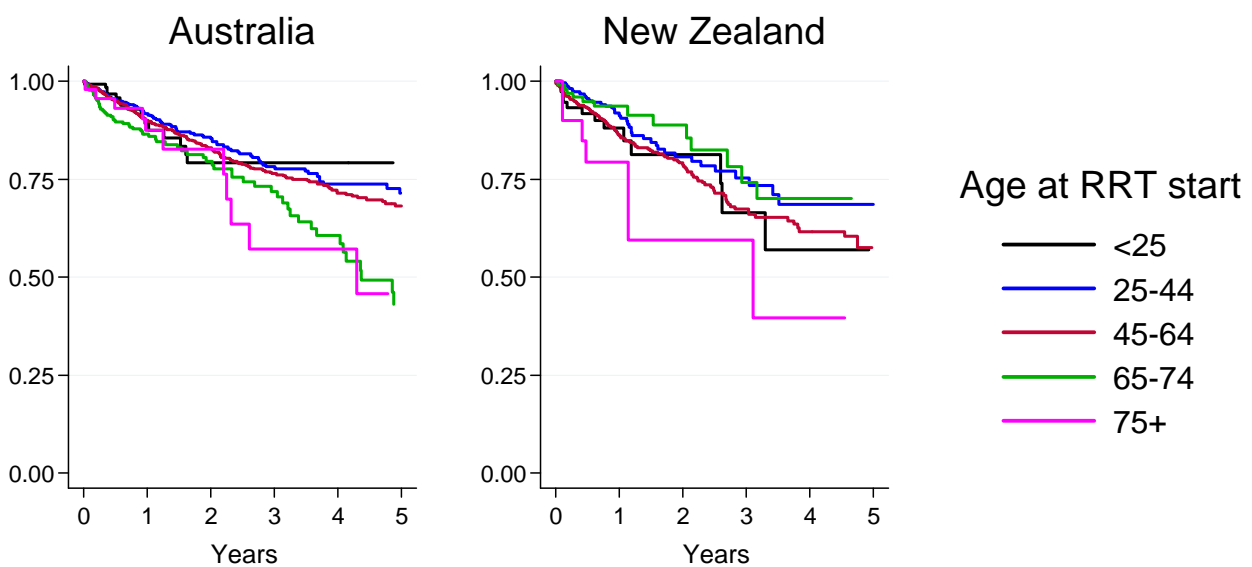

When death of patient is counted as a censoring event (rather than “failure”), the differences between the age groups become less apparent (Figure 5.113). It can be seen that (among those alive and not transplanted) over 75% of home haemodialysis patients continue in this therapy after 2 years. However, as time passes there is a progressive difference which emerges with higher technique failure rates among the older patients.

### Definitions in use

<b>CARI guidelines</b>	<b>Caring for Australasians with Renal Impairment guidelines</b>
<b>Quotidian HD</b>	<b>&gt; 3 sessions/week and/or &gt; 5.5 hours/session</b>
<b>Long Hour HD</b>	<b>≥ 6.5 hours per HD session</b>
<b>High Flux Dialyser</b>	<b>Ultrafiltration coefficient (kuf) &gt;20 ml/hr/mmHg as specified by the manufacturer)</b>
<b>AVF</b>	<b>Native vein arteriovenous fistula</b>
<b>AVG</b>	<b>Synthetic arteriovenous bridge graft</b>
<b>CVC</b>	<b>Central venous HD catheter (Includes both tunnelled and non-tunnelled unless otherwise stated)</b>
<b>Obese</b>	<b>BMI ≥ 30</b>
<b>Morbid Obesity</b>	<b>BMI ≥ 35</b>
